

9 Creating additional files

This button allows you to create various file-types from GPX files. The files will be created in a sub directory of the selected GPX file.

File types also usable on the XT(2).

- Tracks. (GPX format) Tracks are created from selected routes in the GPX file.
To share your routes to users of other GPS models. (EG TomTom)
- Stripped routes. (GPX format) Contains only the Begin, End, Via and shaping points of the route.
To force a recalculation when loaded onto the XT(2).
- Way points (GPX format) The Tracks & Stripped routes don't contain the Way points from the original GPX. Check this if you need them, for example to be able to navigate to a specific routepoint, without using the route. Additionally you can create Way points from the Via, and or Shaping points in the original GPX.
- POI. (GPI format) Creates 'Custom POI'. Custom POI's, or alerts, popup regardless of the route you're driving. They will be displayed with the correct icon, e.g. the chosen icon in Basecamp.
- Trip files. (.trip format) Creates .trip files that can be used right away on the XT(2).

The file types mentioned above will also be created as needed when you use 'Transfer to device'. The difference here is that the files will not be deleted when closing the program.

File types not usable on the XT(2).

- KML Files. The generated files will be usable in Google Earth, or other programs supporting this format. For example Maps.Me, Organic Maps or Google Maps.
- HTML Files. The generated HTML files can be used to share you routes to anyone who is able to open a browser.

Note: To open a KML, HTML file you can double-click on the file in TripManager. For KML you will need an application like Google Earth.
